Chapter 1

2

2.1

I think that by "arc", the author is referring to path. (Spivak uses arc to refer to one-one path.) In that case, this is easy.

3

3.1

The center of a group G is the set of all elements z such that $z \cdot g = g \cdot z$.

If two path classes gives rises to the same isomorphism if and only if $\gamma' \gamma^{-1}$ belongs to the center of the group $\pi(X, x)$.

3.2

We claim the following: this is equivalent to:

Fix a point x; if for all values of y, and all path class γ and γ' connecting x and y, $\gamma' \gamma^{-1}$ be an element of the center of the group.

Basically this is an extension of the result from problem 3.1. The only difference is that we can simply state the equivalence for a fixed x and this would be equivalent for any point in X too.

3.3

Suppose $f \sim g$, then $f \cdot \bar{g} = g \cdot \bar{g} = \mathscr{E}_x \in \pi(X, x)$.

Suppose $f \cdot \bar{g} = \mathscr{E}_x$, then $f \cdot \bar{g} g = \mathscr{E}_x \cdot g \implies f \cdot \mathscr{E}_y = g \implies f \sim g$.

4

TODO 4.1

4.2

Recall that X is Hausdorff if and only if the diagonal $\Delta = \{x \times x | x \in X\}$ is closed.

Given two maps $f, g \colon X \to Y$, then the set $A = \{x \in X | f(x) = g(x)\}$ is closed if Y is Hausdorff. This can be proved by making use of the above observation, since $A = (f \times g)^{-1}(\Delta)$.

Let $f\colon X \to X$ be a retraction mapping from X onto Z and $i\colon X \to X$ be the identity map. Then the points where both these map are equal is clearly the set Z which will become closed.

TODO 4.3

4.4

Suppose A be a retract of X and $r\colon X \to A$ be the corresponding retraction. Then define a function $\phi\colon X \times Y \to A \times Y$ by $\phi(x, y) = (r(x), y)$. This function is clearly continuous and thus forms a retraction mapping from $X \times Y$ onto $A \times Y$.

Suppose that there is a retraction $\phi\colon X \times Y \to A \times Y$. Define a retraction $r\colon X \times A$ by first picking a point $y_0 \in Y$ and by making $r(x) = \pi_1 \circ \phi(x, y_0)$. Once again one can verify that this mapping is a retraction.

4.5

This is easy. Compose the two retraction mappings to get the required retraction.

4.6

Without loss of generality, one can assume that the $(n-1)$ dimensional sphere S^{n-1} is the unit-sphere centered at the origin and the point x_0 is the origin.

Let $X = \mathbb{R}^n - \{0\}$, then define the function $\phi\colon X \times I \to X$ by

$\phi(x, t) = (1 - t)x + t \cdot \frac{x}{\|x\|}$.

One can verify that this is indeed the required deformation retract.

4.7

The center circle.

TODO 4.8

TODO 4.9

4.10

Suppose that f_0 and f_1 be any two path connecting x and y. Consider the path from x to x given by $\gamma = f_0 \cdot f_1^{-1}$.$

Since the space is a deformation retract to a single point, the fundamental group $\pi(X, x)$ is isomorphic to the trivial group $\{e\}$, i.e., γ is identity. This shows that f_0 and f_1 are equivalent.

TODO 4.11

5

5.1

Given a loop $f\colon I \to X$ based on x_0, we need to prove that this belongs to the trivial class.

Suppose $f(I)$ is entirely contained in one of U_i, since U_i is simply connected, the fact that f belongs to trivial class is obvious. We assume that $f(I)$ is contained is not completed contained in a single U_i.

Define a class of open sets $V_i = f^{-1}(U_i)$. Since $[0,1]$ is compact and since V_i is an open cover of $[0,1]$, there exists a real number, ε (the Lebesgue number corresponding to the open cover), such that any set whose diameter is less than ε is completely contained in one of U_i.

Thus we can find a sequence $0 = t_1 < t_2 < \cdots < t_n = 1$ such that the following conditions are satisfied for all i:

(a). $f([t_i, t_{i+1}]) \subset U_j$ for all some j;

(b). $f([t_i, t_{i+1}])$ and $f([t_{i+1}, t_{i+2}])$ are not entirely contained in same U_j for some j.

This can be constructed in the following fashion: pick t_i such that the condition on diameter is satisfied. This guarantees the first condition. If for consecutive intervals lies completely inside a single U_i, simply merge the intervals to produce a larger one; repeat this procedure until the second condition is satisfied.

This basically implies that for every value of i, $f(t_i)$ belongs to the intersection of U_j and U_k for some value of j and k.

Let us denote the path component corresponding to f as β and the ones that correspond to the restriction of f on the sub intervals as β_i. It is easy to see that

$\beta = \beta_1 \cdot \beta_2 \cdot \cdots .$

Since $f(t_i)$ will always belong to the intersection, we can think of a path γ_i that connects $f(t_i)$ and the point x_0. Define the loop classes δ_i in the following manner:

$\delta_1 = \beta_1 \gamma_1,$

$\delta_i = \gamma_{i-1}^{-1} \beta_i \gamma^i$ for $1 < i < n$,

$\delta_n = \gamma_{n-1}^{-1} \beta_n$. (if n is finite.)

It is easy to see that

$\beta = \delta_1 \cdot \delta_2 \cdots .$

Observe that each δ_i is a loop at x_0 and lying entirely inside U_i, i.e., trivial. We have shown that f can be decomposed as loops of trivial classes, i.e., f belongs to the trivial loop class. ■

Special cases

(a). Let X be a topological space and U_1, U_2 be two open sets that cover X that has at least one point in common. Suppose these open sets are simply connected and if $U_1 \cap U_2$ is an arc wise connected space, then X is simply connected.

(b). Let $\{U_i\}$ be a nonempty open cover of X such that $U_i \subset U_j$ whenever $i < j$. Suppose each of U_i are arc connected and simply connected. Then the space X is simply connected.

5.2

We make use of the Stereographic projection of S^n. Let p and $-p$ represent two antipodal points of S^n, then there exists two homeomorphisms $f \colon S^n - \{p\} \to \mathbb{R}^n$ $g \colon S^n - \{-p\} \to \mathbb{R}^n$. This shows that the open subsets $S^n - \{p\}$ and $S^n - \{-p\}$, which has a arc connected intersection whenever $n \geq 2$ (this is not true for $n = 1$), are also simply connected. From previous exercise, we see that S^n is simply connected.

5.3

$R^2 - \{0\}$ is not simply connected while $R^n - \{0\}$ is simply connected for $n > 2$.

5.4

A homeomorphism cannot map a point of S^1 to a point in the interior of E^2. This is because, there is no neighborhood of a point on the boundary that is homeomorphic $\mathbb{R}^2$ while there are neighborhoods of E^2 that are homeomorphic to $\mathbb{R}^2$.

Alternatively, one can see that deleted neighborhoods of a point on the boundary are simply connected while this is not the case with a point on the interior of D^2.

7

7.1

A torus is $S^1 \times S^1$, thus $\pi(S^1 \times S^1) = \mathbb{Z} \times \mathbb{Z}$.

7.2

Consider the retract $r \colon S^1 \times S^1 \to S^1 \times \{p\}$ defined by $r(x, y) = (x, p)$. This is clearly, a continuous map.

Recall that, if A is a deformation retract of X, then the inclusion map induces an isomorphism of $\pi(A, a)$ onto $\pi(X, a)$ for any $a \in A$. Observe that the group $\mathbb{Z} \times \mathbb{Z}$ is not isomorphic to $\mathbb{Z}$ (the first one is cyclic.)

Chapter 2

3

3.1

Let F' denote the subgroup of F that is generated by elements of $\varphi(S)$. Given an Abelian group A, there is a homomorphism g that makes the diagram in the textbook commutative (lazy to draw it here.)

Firstly we shall show that F' shall also satisfy the hypothesis required for free group over S. This can be seen from the fact that the mep $g|_{F'}$ is a homomorphism between F' and A which also makes the diagram (in the book) commutative. From Proposition 3.1, F' and F are isomorphic.

Since F is Abelian, here is a unique homomorphism between F' and F that makes the diagram commutative. Clearly identity is the unique homomorphism, thus $F' = F$.
